

deformation rules:
 $\partial C \sim \partial$
 for any chain C

Example

Geometry problem:

Can these loops be deformed into each other?

Equivalent algebra problem:

= + ∂ (unknown 2-chain)

deformation substitution

Does this equation have a solution?

Recognizing loops algebraically:

The 1-chain C is a sum of closed loops if and only if $\partial C = 0$

Def: The n-chain C is an n-cycle if $\partial C = 0$

Two n-cycles A, B can be deformed into each other if and only if $B = A + \partial F$ for some (n+1)-chain F

i.e. can turn A into B using the deformation substitutions coming from (n+1)-simplices

Therese built a solution from the deformations

∂ (rectangle with vertical line) = (rectangle with diagonal line) + ∂ (triangle)

∂ (rectangle with diagonal line) = (rectangle with vertical line) + ∂ (triangle)

She noticed that

(rectangle with vertical line) - ∂ (rectangle with diagonal line) = (rectangle with diagonal line)

= (rectangle with vertical line) + ∂ (triangle)

(rectangle with vertical line) - ∂ (rectangle with diagonal line) + ∂ (rectangle with diagonal line) = (rectangle with vertical line)

= (rectangle with vertical line)

(rectangle with vertical line) \sim (rectangle with diagonal line) via defm subs

To find a solution more systematically, write the boundary operator as a matrix.

$M_{\partial} =$

		...
1	0	
-1	-1	
-1	-1	
0	1	
0	0	
0	0	

Then the equation we want to solve becomes an integer matrix equation, which we can solve using Gaussian elimination.

= + ∂ (triangle)

$\begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} + M_{\partial} \begin{bmatrix} ? \\ ? \\ ? \end{bmatrix}$

$\begin{bmatrix} -1 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ -1 & -1 \\ -1 & -1 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} -1 \\ 1 \\ 0 \\ 0 \end{bmatrix}$

In this example, the 1-chains have 6 degrees of freedom, and the 1-cycles turn out to have 5. The substitution deformations can move you along 4. Does the last degree of freedom have a geometric interpretation? May be related to the "Dehn twist" operations shown below.
